It's a small freeware to change the colour of an image without changing the colour of the original. It uses many different colour profiles from software that are available free for each system and each hardware. These profiles are used to translate or convert the colours to the colours that the system is capable of producing. It uses colour matching to allow the colours to be converted or changed to the desired colours. The changes are only made on the pixels that are in the selected areas. The changes are made in 3 steps. 1. Changing the Red-Green-Blue colours of the selected pixels. 2. Changing the Cyan-Magenta-Yellow colours of the selected pixels. 3.

Changing the White of the selected pixels. The changes to the White are not done on all the pixels. Only those in the selected areas. The first step changes all the Red-Green-Blue colours in the pixels to the Red, Green and Blue colours that are available to the system. The second step changes all the Cyan-Magenta-Yellow colours in the pixels to the Cyan, Magenta and Yellow colours that are available to the system. The third step changes all the White colours in the pixels to the White that is available to the system. Note: The values of the Red-Green-Blue and Cyan-Magenta-Yellow colours are not given. They should be calculated for each system and hardware. Ipsilateral response for prediction of clinical outcomes in lateral medullary syndrome.
